

20180521: this version introduces the augmentations:

Blue text names functions (black boxes) and the lines in the source crop_yield.py that specify their body

Dropped "outer" variable indices (for YIELD_EST and TOTAL_RAIN).

By default those would have initial values; when loop_plate refers to earlier state, then accesses values of outer var

Initialization of variables are themselves functions that set to values (like deterministic priors)

IF (conditional): outcome of condition is boolean variable (UPDATE_EST.IF1),

and conditional is itself a function that determines value of boolean outcome variable

(which in this case is also function of another variable: TOTAL_RAIN)

Introducing notation for indexed variable names:

<var>@(<index_var>=<offset>)

denotes variable <var> at index to current <index_var>, offset by <offset> (which looks like with be integer <= 0)
